Absolute continuity for some one-dimensional processes

Nicolas Fournier[*], Jacques Printems[*]

July 8, 2008

Abstract

We introduce an elementary method for proving the absolute continuity of the time marginals of one-dimensional processes. It is based on a comparison between the Fourier transform of such time marginals with those of the one-step Euler approximation of the underlying process. We obtain some absolute continuity results for stochastic differential equations with Hölder continuous coefficients. Furthermore, we allow such coefficients to be random and to depend on the whole path of the solution. We also show how it can be extended to some stochastic partial differential equations, and to some Lévy-driven stochastic differential equations. In the cases under study, the Malliavin calculus cannot be used, because the solution in generally not Malliavin-differentiable.

Key words : Absolute continuity, Stochastic differential equations, Lévy processes, Stochastic partial differential equations, Hölder coefficients, Random coefficients.

1 Introduction

In this paper, we introduce a new method for proving the absolute continuity of the time marginals of some one-dimensional processes. The main idea is elementary, and quite rough. It is based on the explicit law of the associated one-step Euler scheme, and to an estimate saying that the process and its Euler scheme remain very close to each other during one step.

As we will see, this method is quite robust, and applies to many processes for which the use of the Malliavin calculus (see Nualart [20], Malliavin [18]) is not possible, because the processes do not have Malliavin derivatives: examples for this are S.D.E.s with Hölder coefficients, S.D.E.s with random coefficients,... However, we are not able, for the moment, to extend it to multi-dimensional processes. The difficulty seems to be that we use some integrability properties of some Fourier transforms, which heavily depends on the dimension.

To illustrate this method, we will consider four types of one-dimensional processes. Let us summarize roughly the results we obtain, and compare them to existing results.

Brownian S.D.E.s with Hölder coefficients. To introduce our method in a simple way, we consider a process satisfying a S.D.E. of the form $dX_t = \sigma(X_t)dB_t + b(X_t)dt$. We assume that b is measurable with at most linear growth, and that σ is Hölder continuous with exponent $\theta > 1/2$. We show that X_t has a density on $\{\sigma \neq 0\}$ as soon as $t > 0$. The proof is very short.
Such a result is probably not far from being already known. In the case where σ is bounded below, Aronson [1] obtains some absolute continuity result assuming only that σ and b are measurable (together with some growth conditions) by analytical methods. Our result might be deduced from [1] by a localization argument, however, we did not succeed in this direction. Anyway, our proof is much more simple.

---

Let us observe that to our knowledge, all the probabilistic papers about this topic assume at least that σ, b are Lipschitz-continuous, see the paper of Bouleau-Hirsch [8] (the case where b is measurable can also be treated by using the Girsanov Theorem).
Finally, let us mention that in [8], one gets the absolute continuity of the law of X_t for all $t > 0$ as soon as $\sigma(x_0) \neq 0$, if $X_0 = x_0$. Such a result cannot hold in full generality for Hölder continuous coefficients: choose $x_0 > 0$, $\sigma(x) = x$, and $b(x) = -sign(x)|x|^\alpha$, for some $\alpha \in (0,1)$. Denote by $\tau_\epsilon = \inf\{t \geq 0, X_t = \epsilon\}$, for $\epsilon \in \mathbb{R}_+$. One can check, using the Itô formula, that for $\epsilon \in (0, x_0)$, $\mathbb{E}[X_{t\wedge\tau_\epsilon}^{1-\alpha}] = x_0^{1-\alpha} - \mathbb{E}[\int_0^{t\wedge\tau_\epsilon}(\frac{\alpha(1-\alpha)}{2}X_s^{1-\alpha} + (1-\alpha))ds] \leq x_0^{1-\alpha} - (1-\alpha)\mathbb{E}[\tau_\epsilon \wedge t]$, whence $\mathbb{E}[\tau_\epsilon] \leq x_0^{1-\alpha}/(1-\alpha)$. As a consequence, $\mathbb{E}[\tau_0] \leq x_0^{1-\alpha}/(1-\alpha)$. But it also holds that $X_{\tau_0+t} = 0$ a.s. for all $t \geq 0$. Thus $\Pr[X_t = 0] > 0$, at least for t large enough.

Brownian S.D.E.s with random coefficients depending on the paths. We consider here a process solving a S.D.E. of the form $dX_t = \sigma(X_t)\kappa(t, (X_u)_{u\leq t}, H_t)dB_t + b(t, (X_u)_{u\leq t}, H_t)dt$, for some auxiliary adapted process H. We assume some Hölder conditions on $\sigma\kappa$, some growth conditions, and that κ is bounded below. We prove the absolute continuity of the law of X_t on the set $\{\sigma \neq 0\}$ for all $t > 0$.
Observe that we do not assume that H is Malliavin-differentiable, which would of course be needed if we wanted to use the Malliavin calculus.
S.D.E.s with random coefficients arise for example in finance. Indeed, stochastic volatility models are now widely used, see e.g. Heston [14], Fouque-Papanicolaou-Sircar [11],... S.D.E.s with coefficients depending on the paths of the solutions arise in random mechanics: if one writes a S.D.E. satisfied by the velocity of a particle, the coefficients will often depend on its position, which is nothing but the integral of its velocity. One can also imagine a particle with position X_t whose diffusion and drift coefficients depend on the length covered by the particle at time t, that is $\sup_{[0,t]} X_s - \inf_{[0,t]} X_s$.
Here again, the result is not far from being known: if $\sigma\kappa$ is bounded below, one may use the result of Gyongy [13], which says that the solution of a S.D.E. (with random coefficients depending on the whole paths of the solution) has the same time marginals as the solution of a S.D.E. with deterministic coefficients depending only on time and position. These coefficients being measurable and uniformly elliptic, one may then use the result of Aronson [1]. However, our method is extremely simple, and we do not have to assume that σ is bounded below.

Stochastic heat equation. We also study the heat equation $\partial_t U = \partial_{xx} U + b(U) + \sigma(U)\dot{W}$ on $\mathbb{R}_+ \times [0,1]$, with Neumann boundary conditions, where W is a space-time white noise, see Walsh [23]. We prove that $U(t,x)$ has a density on $\{\sigma \neq 0\}$ for all $t > 0$, all $x \in [0,1]$, as soon as σ is Hölder continuous with exponent $\theta > 1/2$, and b is measurable and has at most linear growth.
This result shows the robustness of our method: the best absolute continuity result was due to Pardoux-Zhang [21], who assume that b and σ are Lipschitz continuous. Let us however mention that their nondegeneracy condition is very sharp, since they obtain the absolute continuity of $U(t,x)$ for all $t > 0$, all $x \in [0,1]$ assuming only that $\sigma(U(0,x_0)) \neq 0$ for some $x_0 \in [0,1]$ (if $U(0,.)$ is continuous).

Lévy-driven S.D.E.s. We finally consider the S.D.E. $dX_t = \sigma(X_t)dZ_t + b(X_t)dt$, where $(Z_t)_{t\geq 0}$ is a Lévy process without drift and without Brownian part, and with Lévy measure ν. Roughly, we assume that $\int_{|z|\leq\epsilon} z^2\nu(dz) \simeq \epsilon^{2-\lambda}$, for all $\epsilon \in (0,1]$, for some $\lambda \in (3/4, 2)$. We obtain that the law of X_t has a density on $\{\sigma \neq 0\}$ for all $t > 0$, under the following assumption:
(a) if $\lambda \in (3/2, 2)$, b is measurable and has at most linear growth, and σ is Hölder continuous with exponent $\theta > 1/2$;
(b) if $\lambda \in [1, 3/2]$, b and σ are Hölder continuous with exponents $\alpha > 3/2 - \lambda$ and $\theta > 1/2$;
(c) if $\lambda \in (3/4, 1)$, b, σ are Hölder continuous with exponent $\theta > 3/(2\lambda) - 1$.
This result seems to be the first absolute continuity result for jumping S.D.E.s with non Lipschitz coefficients. Observe that in some cases we allow the drift coefficient to be only measurable, even when the driving Lévy process has no Brownian part. Such a result cannot be obtained using a trick like Girsanov's Theorem (because even the law of such a Lévy process $(Z_t)_{t\in[0,1]}$ and that of $(Z_t + t)_{t\in[0,1]}$ are clearly not equivalent). To our knowledge, this gives the first absolute continuity result for Lévy-driven S.D.E.s with measurable drift.

Observe also that we allow the intensity measure of the Poissonian part to be singular: even without Brownian part and without drift, our result yields some absolute continuity for Lévy-driven S.D.E.s, even when the Lévy measure of the driving process is completely singular. Such cases are not included in the famous works of Bichteler-Jacod [7], Bichteler-Gravereaux-Jacod [6]. Picard [22] obtained some very complete results in that direction, for S.D.E.s with smooth coefficients. Notice that Picard obtains his results for any $\lambda \in (0,2)$: our assumption is quite heavy, since we have to restrict our study to the case where $\lambda > 3/4$.
Let us finally mention a completely different approach developped by Denis [10], Nourdin-Simon [19], Bally [2] and others, where singular Lévy measures are allowed when the drift coefficient is sufficiently non constant.

We will frequently use the following classical Lemma.

Lemma 1.1 *For* μ *a nonnegative finite measure on* $\mathbb{R}$*, we denote by* $\widehat{\mu}(\xi) = \int_{\mathbb{R}} e^{i\xi x}\mu(dx)$ *its Fourier transform (for all* $\xi \in \mathbb{R}$*). If* $\int_{\mathbb{R}} |\widehat{\mu}(\xi)|^2 d\xi < \infty$*, then* μ *has a density with respect to the Lebesgue measure.*

Proof For $n \geq 1$, consider $\mu_n = \mu \star g_n$, where g_n is the centered Gaussian distribution with variance $1/n$. Then of course, $|\widehat{\mu}_n(\xi)| \leq |\widehat{\mu}(\xi)|$. Furthermore, μ_n has a density $f_n \in L^1 \cap L^\infty(\mathbb{R}, dx)$ (for each fixed $n \geq 1$), so that we may apply the Plancherel equality, which yields $\int_{\mathbb{R}} f_n^2(x)dx = (2\pi)^{-1}\int_{\mathbb{R}} |\widehat{\mu}_n(\xi)|^2 d\xi \leq (2\pi)^{-1}\int_{\mathbb{R}} |\widehat{\mu}(\xi)|^2 d\xi =: C < \infty$. Due to the weak compactness of the balls of $L^2(\mathbb{R}, dx)$, we may extract a subsequence n_k and find a function $f \in L^2(\mathbb{R}, dx)$ such that f_{n_k} goes weakly in $L^2(\mathbb{R}, dx)$ to f. But on the other hand, $\mu_n(dx) = f_n(x)dx$ tends weakly (in the sense of measures) to μ. As a consequence, μ is nothing but $f(x)dx$. ☐

Observe here that this Lemma is optimal. Indeed, the fact that $\widehat{\mu}$ belongs to L^p, with $p > 2$, does not imply that μ has a density, see counter-examples in Kahane-Salem [16]. The following localization argument will also be of constant use.

Lemma 1.2 *For* $\delta > 0$*, we introduce a function* $f_\delta : \mathbb{R}_+ \mapsto [0,1]$*, vanishing on* $[0,\delta]$*, positive on* (δ, ∞)*, and globally Lipschitz continuous (with Lipschitz constant* 1*).*
Consider a probability measure μ *on* $\mathbb{R}$ *and a function* $\sigma : \mathbb{R} \mapsto \mathbb{R}_+$*. Assume that for each* $\delta > 0$*, the measure* $\mu_\delta(dx) = f_\delta(\sigma(x))\mu(dx)$ *has a density. Thus* μ *has a density on* $\{x \in \mathbb{R}, \sigma(x) > 0\}$*.*

Proof Let $A \subset \mathbb{R}$ be a Borel set with Lebesgue measure 0. We have to prove that $\mu(A \cap \{\sigma > 0\}) = 0$. For each $\delta > 0$, the measures $\mathbf{1}_{\{\sigma(x) > \delta\}}\mu(dx)$ and $\mu_\delta(dx)$ are clearly equivalent. By assumption, $\mu_\delta(A) = 0$ for each $\delta > 0$, whence $\mu(A \cap \{\sigma > \delta\}) = 0$. Hence, $\mu(A \cap \{\sigma > 0\}) = \lim_{\delta \to 0} \mu(A \cap \{\sigma > \delta\}) = 0$. ☐

The different sections of this paper are almost independent. In Section 2, we consider the case of simple Brownian S.D.E.s. Section 3 is devoted to Brownian S.D.E.s with random coefficients depending on the whole path of the solution. The stochastic heat equation is treated in Section 4. Finally, we consider some Lévy-driven S.D.E.s in Section 5.

2 Simple Brownian S.D.E.s

We consider a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)$ and a $(\mathcal{F}_t)_{t \geq 0}$-Brownian motion $(B_t)_{t \geq 0}$. For $x \in \mathbb{R}$ and $\sigma, b : \mathbb{R} \mapsto \mathbb{R}$, we consider the one-dimensional S.D.E.

$$X_t = x + \int_0^t \sigma(X_s)dB_s + \int_0^t b(X_s)ds. \tag{2.1}$$

Our aim in this section is to prove the following result.

Theorem 2.1 *Assume that* σ *is Hölder continuous with exponent* $\theta \in (1/2, 1]$*, and that* b *is measurable and has at most linear growth. Consider a continuous* $(\mathcal{F}_t)_{t \geq 0}$*-adapted solution* $(X_t)_{t \geq 0}$ *to (2.1). Then for all* $t > 0$*, the law of* X_t *has a density on the set* $\{x \in \mathbb{R}, \sigma(x) \neq 0\}$*.*

Observe that the (weak or strong) existence of solutions to (2.1) does not hold under the sole assumptions of Theorem 2.1. However, at least weak existence holds if one assumes additionally that b is continuous or that σ is bounded below, see Karatzas-Shreve [17].

Proof By a scaling argument, it suffices to consider the case $t = 1$. We divide the proof into three parts.

Step 1. For $\epsilon \in (0,1)$, we consider the random variable

$$Z_\epsilon := X_{1-\epsilon} + \int_{1-\epsilon}^1 \sigma(X_{1-\epsilon}) dB_s = X_{1-\epsilon} + \sigma(X_{1-\epsilon})(B_1 - B_{1-\epsilon}).$$

Conditioning with respect to $\mathcal{F}_{1-\epsilon}$, we get, for all $\xi \in \mathbb{R}$,

$$|\mathbb{E}\Big[e^{i\xi Z_\epsilon} | \mathcal{F}_{1-\epsilon}\Big]| = |\exp\left(i\xi X_{1-\epsilon} - \epsilon\sigma^2(X_{1-\epsilon})\xi^2/2\right)| = \exp\left(-\epsilon\sigma^2(X_{1-\epsilon})\xi^2/2\right).$$

Step 2. Using classical arguments (Doob's inequality and Gronwall Lemma), and the fact that σ and b have at most linear growth one may show that there is a constant C such that for all $0 \le s \le t \le 1$,

$$\mathbb{E}\left[\sup_{[0,1]} X_t^2\right] \le C, \quad \mathbb{E}\left[(X_t - X_s)^2\right] \le C(t-s). \tag{2.2}$$

Next, since σ is Hölder continuous with index $\theta \in (1/2, 1]$ and since b has at most linear growth, we get, for all $\epsilon \in (0,1)$,

$$\begin{aligned}
\mathbb{E}[(X_1 - Z_\epsilon)^2] &\le 2\int_{1-\epsilon}^1 \mathbb{E}\left[(\sigma(X_s) - \sigma(X_{1-\epsilon}))^2\right] ds + 2\mathbb{E}\left[\left(\int_{1-\epsilon}^1 b(X_s) ds\right)^2\right] \\
&\le C\int_{1-\epsilon}^1 \mathbb{E}\left[|X_s - X_{1-\epsilon}|^{2\theta}\right] ds + 2\epsilon \int_{1-\epsilon}^1 \mathbb{E}[b^2(X_s)] ds \\
&\le C\int_{1-\epsilon}^1 \mathbb{E}\left[|X_s - X_{1-\epsilon}|^2\right]^\theta ds + C\epsilon \int_{1-\epsilon}^1 \mathbb{E}[1 + X_s^2] ds \\
&\le C\epsilon^{1+\theta} + C\epsilon^2 \le C\epsilon^{1+\theta},
\end{aligned}$$

where we used (2.2).

Step 3. Let $\delta > 0$ be fixed, consider the function f_δ defined in Lemma 1.2, and the measure $\mu_{\delta,X_1}(dx) = f_\delta(|\sigma(x)|)\mu_{X_1}(dx)$, where μ_{X_1} is the law of X_1. Then for all $\xi \in \mathbb{R}$, all $\epsilon \in (0,1)$, we may write

$$\begin{aligned}
|\widehat{\mu_{\delta,X_1}}(\xi)| &= |\mathbb{E}[e^{i\xi X_1} f_\delta(|\sigma(X_1)|)]| \\
&\le |\mathbb{E}[e^{i\xi X_1} f_\delta(|\sigma(X_{1-\epsilon})|)]| + \mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|] \\
&\le |\mathbb{E}[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|)]| + |\xi|\mathbb{E}[|X_1 - Z_\epsilon|] + \mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|],
\end{aligned}$$

where we used the inequality $|e^{i\xi x} - e^{i\xi z}| \le |\xi|.|x - z|$ and the fact that f_δ is bounded by 1. First, Step 1 implies that

$$\begin{aligned}
\left|\mathbb{E}\left[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|)\right]\right| &\le \mathbb{E}\left[\left|\mathbb{E}\left[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|) | \mathcal{F}_{1-\epsilon}\right]\right|\right] \\
&\le \mathbb{E}\left[f_\delta(|\sigma(X_{1-\epsilon})|) e^{-\epsilon\sigma^2(X_{1-\epsilon})\xi^2/2}\right] \le \exp(-\epsilon\delta^2\xi^2/2),
\end{aligned}$$

since f_δ is bounded by 1 and vanishes on $[0,\delta]$. Step 2 implies that $|\xi|\mathbb{E}[|X_1 - Z_\epsilon|] \le C|\xi|\epsilon^{(1+\theta)/2}$. Since f_δ is Lipschitz continuous and σ is Hölder continuous with index $\theta \in (1/2, 1]$, we deduce from (2.2) that $\mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|] \le C\mathbb{E}[|X_1 - X_{1-\epsilon}|^\theta] \le C\epsilon^{\theta/2}$.
As a conclusion, we deduce that for all $\xi \in \mathbb{R}$, for all $\epsilon \in (0,1)$,

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le \exp(-\epsilon\delta^2\xi^2/2) + C|\xi|\epsilon^{(1+\theta)/2} + C\epsilon^{\theta/2}.$$

For each $|\xi| \geq 1$ fixed, we apply this formula with the choice $\epsilon := (\log|\xi|)^2/\xi^2 \in (0,1)$. This gives

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \leq \exp(-\delta^2(\log|\xi|)^2/2) + C(\log|\xi|)^{1+\theta}/|\xi|^\theta + C(\log|\xi|)^\theta/|\xi|^\theta.$$

This holding for all $|\xi| \geq 1$, and $\widehat{\mu_{\delta,X_1}}$ being bounded by 1, we get that $\int_{\mathbb{R}} |\widehat{\mu_{\delta,X_1}}(\xi)|^2 d\xi < \infty$, since $\theta > 1/2$ by assumption. Lemma 1.1 implies that the measure μ_{δ,X_1} has a density, for each $\delta > 0$. Lemma 1.2 allows us to conclude that μ_{X_1} has a density on $\{|\sigma| > 0\}$. □

3 Brownian S.D.E.s with random coefficients

We start again with a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, P)$ a $(\mathcal{F}_t)_{t\geq 0}$-Brownian motion $(B_t)_{t\geq 0}$. To model the randomness of the coefficients, we consider an auxiliary predictable process $(H_t)_{t\geq 0}$, with values in some normed space $(\mathcal{S}, ||\ .\ ||)$. Then we consider $\sigma : \mathbb{R} \mapsto \mathbb{R}$ and two measurable maps $\kappa, b : \mathcal{A} \mapsto \mathbb{R}$, where

$$\mathcal{A} := \{(s, (x_u)_{u\leq s}, h),\ s \geq 0, (x_u)_{u\geq 0} \in C(\mathbb{R}_+, \mathbb{R}), h \in \mathcal{S}\},$$

and the following one-dimensional S.D.E.

$$X_t = x + \int_0^t \sigma(X_s)\kappa(s, (X_u)_{u\leq s}, H_s)dB_s + \int_0^t b(s, (X_u)_{u\leq s}, H_s)ds. \tag{3.1}$$

Here again, the existence of solutions to such a general equation does of course not always hold, even under the assumptions below. However, there are many particular cases for which the (weak or strong) existence can be proved by classical methods (Picard iteration, martingale problems, change of probability, change of time, ...)

Theorem 3.1 *Assume that the auxiliary process H satisfies, for some $\eta > 1/2$, for all $0 \leq s \leq t \leq T$,*

$$\mathbb{E}\left[||H_t||^2\right] \leq C_T \quad \textit{and} \quad \mathbb{E}\left[||H_t - H_s||^2\right] \leq C_T(t-s)^\eta. \tag{3.2}$$

Assume also that $\kappa\sigma$ and b have at most linear growth, that is for all $0 \leq t \leq T$, all $(x_u)_{u\geq 0} \in C(\mathbb{R}_+, \mathbb{R})$, all $h \in \mathcal{S}$,

$$|\sigma(x_t)\kappa(t, (x_u)_{u\leq t}, h)| + |b(t, (x_u)_{u\leq t}, h)| \leq C_T(1 + \sup_{[0,t]} |x_u| + ||h||), \tag{3.3}$$

that σ is Hölder continuous with index $\alpha \in (1/2, 1]$, and that for some $\theta_1 \in (1/4, 1]$, $\theta_2 \in (1/2, 1]$, and $\theta_3 \in (1/2\eta, 1]$, for all $0 \leq s \leq t \leq T$, all $(x_u)_{u\geq 0} \in C(\mathbb{R}_+, \mathbb{R})$, all $h, h' \in \mathcal{S}$,

$$|\sigma(x_t)\kappa(t, (x_u)_{u\leq t}, h) - \sigma(x_s)\kappa(s, (x_u)_{u\leq s}, h')| \leq C_T\left((t-s)^{\theta_1} + \sup_{u\in[s,t]} |x_u - x_s|^{\theta_2} + ||h - h'||^{\theta_3}\right). \tag{3.4}$$

Finally, assume that κ is bounded below by some constant $\kappa_0 > 0$. Consider a continuous $(\mathcal{F}_t)_{t\geq 0}$-adapted solution $(X_t)_{t\geq 0}$ to (3.1). Then the law of X_t has a density on $\{x \in \mathbb{R},\ \sigma(x) \neq 0\}$ as soon as $t > 0$.

Notice that (3.2) does not imply that H is a.s. continuous: it is just a sort of L^2-continuity. Observe also that we assume no regularity about the drift coefficient b. This is not so surprising, thinking about the Girsanov Theorem. However, the Girsanov Theorem might be difficult to use in such a context, due to the randomness of the coefficients (a change of probability also changes the law of the auxiliary process). Let us briefly illustrate (3.4).

Example 3.2 *(a) Let $\sigma(x_s)\kappa(s, (x_u)_{u\leq s}, h) = \phi(s, x_s, \sup_{[0,s]} \varphi(x_u), h)$, with $\phi : \mathbb{R}_+ \times \mathbb{R} \times \mathbb{R} \times \mathcal{S} \mapsto \mathbb{R}$ satisfying $|\phi(s, x, m, h) - \phi(s', x', m', h')| \leq C(|s-s'|^{\theta_1} + |x-x'|^{\theta_2} + |m-m'|^\zeta + ||h-h'||^{\theta_3})$ and $\varphi : \mathbb{R} \mapsto \mathbb{R}$ satisfying $|\varphi(x) - \varphi(x')| \leq C|x - x'|^r$, with $\zeta r \geq \theta_2$. Then $\sigma\kappa$ satisfies (3.4).*
(b) Let $\sigma(x_s)\kappa(s, (x_u)_{u\leq s}, h) = \phi(s, x_s, \int_0^s \varphi(x_u)du, h)$ with $\phi : \mathbb{R}_+ \times \mathbb{R} \times \mathbb{R} \times \mathcal{S} \mapsto \mathbb{R}$ satisfying the condition $|\phi(s, x, m, h) - \phi(s', x', m', h')| \leq C(|s - s'|^{\theta_1} + |x - x'|^{\theta_2} + |m - m'|^{\theta_1} + ||h - h'||^{\theta_3})$ and with $\varphi : \mathbb{R} \mapsto \mathbb{R}$ bounded. Then $\sigma\kappa$ satisfies (3.4).

Proof The scheme of the proof is exactly the same as that of Theorem 2.1. For the sake of simplicity, we show the result only when $t = 1$.

Step 1. For $\epsilon \in (0,1)$, we consider the random variable

$$Z_\epsilon := X_{1-\epsilon} + \int_{1-\epsilon}^{1} \sigma(X_{1-\epsilon})\kappa(1-\epsilon, (X_u)_{u\le 1-\epsilon}, H_{1-\epsilon})dB_s.$$

Conditioning with respect to $\mathcal{F}_{1-\epsilon}$ and using that $\kappa \ge \kappa_0$ we get, for all $\xi \in \mathbb{R}$,

$$\begin{aligned}|\mathbb{E}\Big[e^{i\xi Z_\epsilon}|\mathcal{F}_{1-\epsilon}\Big]| =& | \exp\left(i\xi X_{1-\epsilon} - \epsilon\sigma^2(X_{1-\epsilon})\kappa^2(1-\epsilon, (X_u)_{u\le 1-\epsilon}, H_{1-\epsilon})\xi^2/2\right)| \\ \le& \exp\left(-\epsilon\kappa_0^2\sigma^2(X_{1-\epsilon})\xi^2/2\right).\end{aligned}$$

Step 2. Using Doob's inequality, the Gronwall Lemma, (3.3) and (3.2), one easily shows that for all $0 \le s \le t \le 1$,

$$\mathbb{E}\left[\sup_{[0,1]} X_t^2\right] \le C, \quad \mathbb{E}\left[\sup_{u\in[s,t]} (X_u - X_s)^2\right] \le C(t-s). \tag{3.5}$$

Next, using (3.4), (3.3), (3.5) and (3.2) we get for all $\epsilon \in (0,1)$,

$$\begin{aligned}\mathbb{E}[(X_1 - Z_\epsilon)^2] \le& 2\int_{1-\epsilon}^{1} \mathbb{E}\left[(\sigma(X_s)\kappa(s,(X_u)_{u\le s}, H_s) - \sigma(X_{1-\epsilon})\kappa(1-\epsilon,(X_u)_{u\le 1-\epsilon}, H_{1-\epsilon}))^2\right] ds \\ &+ 2\mathbb{E}\left[\left(\int_{1-\epsilon}^{1} b(s,(X_u)_{u\le s}, H_s)ds\right)^2\right] \\ \le& C\int_{1-\epsilon}^{1} \mathbb{E}\left[(s-(1-\epsilon))^{2\theta_1} + \sup_{u\in[1-\epsilon,s]} |X_u - X_{1-\epsilon}|^{2\theta_2} + ||H_s - H_{1-\epsilon}||^{2\theta_3}\right] ds \\ &+ 2\epsilon \int_{1-\epsilon}^{1} \mathbb{E}[b^2(s,(X_u)_{u\le s}, H_s)]ds \\ \le& C\epsilon^{1+2\theta_1} + C\epsilon\mathbb{E}\left[\sup_{u\in[1-\epsilon,1]} |X_u - X_{1-\epsilon}|^2\right]^{\theta_2} + C\epsilon \sup_{u\in[1-\epsilon,1]} \mathbb{E}[||H_u - H_{1-\epsilon}||^2]^{\theta_3} \\ &+ C\epsilon\int_{1-\epsilon}^{1} \mathbb{E}[1 + \sup_{u\in[0,s]} X_u^2 + ||H_s||^2]ds \\ \le& C\epsilon^{1+2\theta_1} + C\epsilon^{1+\theta_2} + C\epsilon^{1+\eta\theta_3} + C\epsilon^2 \le C\epsilon^{1+\theta},\end{aligned}$$

where $\theta := \min(2\theta_1, \theta_2, \eta\theta_3, 1) \in (1/2, 1]$ by assumption.

Step 3. Let $\delta > 0$ be fixed, consider the function f_δ of Lemma 1.2 and the measure $\mu_{\delta,X_1}(dx) = f_\delta(|\sigma(x)|)\mu_{X_1}(dx)$, where μ_{X_1} is the law of X_1. Then as in the proof of Theorem 2.1, we may write, for all $\xi \in \mathbb{R}$, all $\epsilon \in (0,1)$,

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le |\mathbb{E}[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|)]| + |\xi|\mathbb{E}[|X_1 - Z_\epsilon|] + \mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|].$$

Exactly as in the proof of Theorem 2.1, using that σ is Hölder continuous with exponent $\alpha \in (1/2, 1]$, that f_δ is bounded by 1, Lipschitz continuous, and vanishes on $[0,\delta]$, we obtain from Steps 1 and 2 that for all $\epsilon \in (0,1)$,

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le \exp(-\epsilon\kappa_0^2\delta^2\xi^2/2) + C|\xi|\epsilon^{(1+\theta)/2} + C\epsilon^{\alpha/2}.$$

For each $|\xi| \ge 1$ fixed, we apply this formula with the choice $\epsilon := (\log|\xi|)^2/\xi^2 \in (0,1)$, and deduce as in the proof of Theorem 2.1 that $\int_{\mathbb{R}} |\widehat{\mu_{\delta,X_1}}(\xi)|^2 d\xi < \infty$, because $\theta > 1/2$ and $\alpha > 1/2$. Due to Lemma 1.1, this implies that μ_{δ,X_1} has a density, for each $\delta > 0$. Thus μ_{X_1} has a density on $\{|\sigma| > 0\}$ thanks to Lemma 1.2. $\square$

4 Stochastic heat equation

On a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, P)$, we consider a $(\mathcal{F}_t)_{t\geq 0}$-space-time white noise $W(dt, dx)$ on $\mathbb{R}_+ \times [0,1]$, based on $dtdx$, see Walsh [23]. For two functions $\sigma, b : \mathbb{R} \mapsto \mathbb{R}$, we consider the stochastic heat equation with Neumann boundary conditions

$$\partial_t U(t,x) = \partial_{xx} U(t,x) + b(U(t,x)) + \sigma(U(t,x))\dot{W}(t,x), \quad \partial_x U(t,0) = \partial_x U(t,1) = 0, \tag{4.1}$$

with some initial condition $U(0,x) = U_0(x)$ for some deterministic $U_0 \in L^\infty([0,1])$.

Consider the heat kernel $G_t(x,y) := \frac{1}{\sqrt{4\pi t}} \sum_{n\in\mathbb{Z}} \left[e^{\frac{-(y-x-2n)^2}{4t}} + e^{\frac{-(y+x-2n)^2}{4t}} \right]$. Following the ideas of Walsh [23], we say that a continuous $(\mathcal{F}_t)_{t\geq 0}$-adapted process $(U(t,x))_{t>0, x\in[0,1]}$ is a weak solution to (4.1) if a.s., for all $t > 0$, all $x \in [0,1]$,

$$\begin{aligned} U(t,x) = & \int_0^1 G_t(x,y) U_0(y) dy + \int_0^t \int_0^1 G_{t-s}(x,y) b(U(s,y)) dy ds \\ & + \int_0^t \int_0^1 G_{t-s}(x,y) \sigma(U(s,y)) W(ds, dy). \end{aligned} \tag{4.2}$$

We will show in this section the following result.

Theorem 4.1 *Assume that b is measurable and has at most linear growth, and that σ is Hölder continuous with exponent $\theta \in (1/2, 1]$. Consider a continuous $(\mathcal{F}_t)_{t\geq 0}$-adapted weak solution $(U(t,x))_{t>0,x\in[0,1]}$ to (4.1). Then for all $x \in [0,1]$, all $t > 0$, the law of $U(t,x)$ has a density on $\{u \in \mathbb{R},\ \sigma(u) \neq 0\}$.*

The existence of solutions is again not proved under the sole assumptions of Theorem 4.1. One can mention Gatarek-Goldys [12] from which we obtain the weak existence of a solution assuming additionally that b is continuous. On the other hand, Bally-Gyongy-Pardoux [3] have proved the existence of a solution for a (locally) Lipschitz continuous diffusion coefficient σ bounded below and a (locally) bounded measurable drift coefficient b.

We will use the following estimates about the heat kernel, which can be found in Bally-Pardoux [4, Appendix] and Bally-Millet-Sanz [5, Lemma B1]. For some constants $0 < c < C$, for all $\epsilon \in (0,1)$, all $x, y \in [0,1]$, all $0 \leq s \leq t \leq 1$,

$$c\sqrt{\epsilon} \leq \kappa_\epsilon(x) := \int_{1-\epsilon}^1 \int_{0\vee(x-\sqrt{\epsilon})}^{1\wedge(x+\sqrt{\epsilon})} G^2_{1-u}(x,z) dz du \leq \int_{1-\epsilon}^1 \int_0^1 G^2_{1-u}(x,z) dz du \leq C\sqrt{\epsilon}, \tag{4.3}$$

$$\int_0^t \int_0^1 (G_{t-u}(x,z) - G_{t-u}(y,z))^2 dz du \leq C|x-y|, \tag{4.4}$$

$$\int_0^s \int_0^1 (G_{t-u}(x,z) - G_{s-u}(x,z))^2 dz du + \int_s^t \int_0^1 G^2_{t-u}(x,z) dz du \leq C|t-s|^{1/2}. \tag{4.5}$$

Proof We assume that $t = 1$ for simplicity, and we fix $x \in [0,1]$.

Step 1. For $\epsilon \in (0,1)$, let

$$\begin{aligned} Z_\epsilon := & \int_0^1 G_1(x,y) U_0(y) dy + \int_0^{1-\epsilon} \int_0^1 G_{1-s}(x,y) b(U(s,y)) dy ds \\ & + \int_0^{1-\epsilon} \int_0^1 G_{1-s}(x,y) \sigma(U(s,y)) W(ds,dy) + \int_{1-\epsilon}^1 \int_0^1 G_{1-s}(x,y) \sigma(U(1-\epsilon,y)) W(ds,dy). \end{aligned}$$

As usual, we observe that

$$\begin{aligned} |\mathbb{E}[e^{i\xi Z_\epsilon} | \mathcal{F}_{1-\epsilon}]| & \leq \exp\left(-|\xi|^2 \int_{1-\epsilon}^1 \int_0^1 G^2_{1-s}(x,y) \sigma^2(U(1-\epsilon,y)) dy ds \right) \\ & \leq \exp\left(-\kappa_\epsilon(x) Y_\epsilon |\xi|^2 \right), \end{aligned}$$

where, recalling (4.3),

$$Y_\epsilon := \frac{1}{\kappa_\epsilon(x)} \int_{1-\epsilon}^{1} \int_{0\vee(x-\sqrt{\epsilon})}^{1\wedge(x+\sqrt{\epsilon})} G_{1-s}^2(x,y)\sigma^2(U(1-\epsilon,y))dyds.$$

Step 2. Using some classical computations involving (4.3)-(4.4)-(4.5), as well as the fact that $t,x \mapsto \int_0^1 G_t(x,y)U_0(y)dy$ is of class C_b^∞ on $(t_0,1]\times[0,1]$ for all $t_0\in(0,1)$, we get, for some constant C,

$$\forall\, t\in[0,1],\ \forall\, y\in[0,1],\quad \mathbb{E}[U^2(t,y)]\le C; \tag{4.6}$$

$$\forall\, s,t\in[1/2,1],\ \forall\, y\in[0,1],\quad \mathbb{E}[(U(t,y)-U(s,y))^2]\le C|t-s|^{1/2}; \tag{4.7}$$

$$\forall\, t\in[1/2,1],\ \forall\, y,z\in[0,1],\quad \mathbb{E}[(U(t,y)-U(t,z))^2]\le C|y-z|. \tag{4.8}$$

Step 2.1. We now prove that for all $\epsilon\in(0,1/2)$,

$$\mathbb{E}[(U(1,x)-Z_\epsilon)^2]\le C\epsilon^{(1+\theta)/2}.$$

Since σ is Hölder continuous, and since b has at most linear growth, using (4.6) and (4.7),

$$\begin{aligned}
\mathbb{E}[(U(1,x)-Z_\epsilon)^2] \le& 2\mathbb{E}\left[\left(\int_{1-\epsilon}^1\int_0^1 G_{1-s}(x,y)b(U(s,y))dyds\right)^2\right]\\
&+2\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)\mathbb{E}\left[(\sigma(U(s,y))-\sigma(U(1-\epsilon,y)))^2\right]dyds\\
\le& 2\epsilon\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)\mathbb{E}\left[b^2(U(s,y))\right]dyds\\
&+C\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)\mathbb{E}\left[|U(s,y)-U(1-\epsilon,y)|^{2\theta}\right]dyds\\
\le& C\epsilon\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)\mathbb{E}\left[1+U^2(s,y)\right]dyds\\
&+C\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)\mathbb{E}\left[|U(s,y)-U(1-\epsilon,y)|^2\right]^\theta dyds\\
\le& C\epsilon\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)dyds + C\epsilon^{\theta/2}\int_{1-\epsilon}^1\int_0^1 G_{1-s}^2(x,y)dyds\\
\le& C\epsilon^{3/2}+C\epsilon^{(1+\theta)/2}\le C\epsilon^{(1+\theta)/2},
\end{aligned}$$

where we finally used (4.3).
Step 2.2. We now check that there is a constant C such that, for all $\epsilon\in(0,1/2)$,

$$A_\epsilon := \mathbb{E}\left[\left|\sigma^2(U(1,x))-Y_\epsilon\right|\right]\le C\epsilon^{\theta/4}.$$

We have

$$\begin{aligned}
A_\epsilon &= \frac{1}{\kappa_\epsilon(x)}\mathbb{E}\left[\left|\int_{1-\epsilon}^1\int_{0\vee(x-\sqrt{\epsilon})}^{1\wedge(x+\sqrt{\epsilon})} G_{1-s}^2(x,y)[\sigma^2(U(1,x))-\sigma^2(U(1-\epsilon,y))]dyds\right|\right]\\
&\le \frac{1}{\kappa_\epsilon(x)}\int_{1-\epsilon}^1\int_{0\vee(x-\sqrt{\epsilon})}^{1\wedge(x+\sqrt{\epsilon})} G_{1-s}^2(x,y)\mathbb{E}\left[\left|\sigma^2(U(1,x))-\sigma^2(U(1-\epsilon,y))\right|\right]dyds\\
&\le \sup_{y\in[x-\sqrt{\epsilon},x+\sqrt{\epsilon}],}\mathbb{E}\left[\left|\sigma^2(U(1,x))-\sigma^2(U(1-\epsilon,y))\right|\right].
\end{aligned}$$

But using that σ is Hölder continuous and has at most linear growth, using (4.6), (4.7) and (4.8), we deduce that for all $y \in [x-\sqrt{\epsilon}, x+\sqrt{\epsilon}]$,

$$\begin{aligned}\mathbb{E}\left[|\sigma^2(U(1,x))-\sigma^2(U(1-\epsilon,y))|\right] \le{}& \mathbb{E}\left[|\sigma(U(1,x))-\sigma(U(1-\epsilon,y))|^2\right]^{1/2}\\ &\times \mathbb{E}\left[|\sigma(U(1,x))+\sigma(U(1-\epsilon,y))|^2\right]^{1/2}\\ \le{}& C\mathbb{E}\left[|U(1,x)-U(1-\epsilon,y)|^{2\theta}\right]^{1/2}\\ \le{}& C\mathbb{E}\left[|U(1,x)-U(1-\epsilon,y)|^{2}\right]^{\theta/2} \le C(\epsilon^{1/2}+|x-y|)^{\theta/2} \le C\epsilon^{\theta/4},\end{aligned}$$

which concludes the step.

Step 3. Denote by $\mu_{U(1,x)}$ the law of $U(1,x)$. For $\delta > 0$, consider f_δ as in Lemma 1.2, and set $\mu_{\delta,U(1,x)}(du) = f_\delta(\sigma^2(u))\mu_{U(1,x)}(du)$. For all $\xi \in \mathbb{R}$, all $\epsilon \in (0,1/2)$, we may write, as in the proof of Theorem 2.1,

$$\begin{aligned}|\widehat{\mu_{\delta,U(1,x)}}(\xi)| ={}&|\mathbb{E}[e^{i\xi U(1,x)}f_\delta(\sigma^2((U(1,x))))]|\\ \le{}&\left|\mathbb{E}\left[e^{i\xi Z_\epsilon}f_\delta\left(Y_\epsilon\right)\right]\right| + |\xi|\mathbb{E}[|U(1,x)-Z_\epsilon|] + \mathbb{E}\left[\left|f_\delta(\sigma^2(U(1,x))) - f_\delta\left(Y_\epsilon\right)\right|\right].\end{aligned}$$

Using Steps 1, 2.1, and 2.2, observing that Y_ϵ is $\mathcal{F}_{1-\epsilon}$-measurable, and recalling that f_δ is bounded by 1 and vanishes on $[0,\delta]$, we get

$$|\widehat{\mu_{\delta,U(1,x)}}(\xi)| \le e^{-\kappa_\epsilon(x)\delta\xi^2} + C|\xi|\epsilon^{(1+\theta)/4} + C\epsilon^{\theta/4} \le e^{-c\delta\sqrt{\epsilon}\xi^2} + C|\xi|\epsilon^{(1+\theta)/4} + C\epsilon^{\theta/4},$$

using (4.3) for the last inequality. For each $|\xi| \ge 1$, we choose $\epsilon := (\log|\xi|)^4/\xi^4 \in (0,1/2)$, and get

$$|\widehat{\mu_{\delta,U(1,x)}}(\xi)| \le \exp\left(-c\delta(\log|\xi|)^2\right) + C(\log|\xi|)^{1+\theta}/|\xi|^\theta + C(\log|\xi|)^\theta/|\xi|^\theta.$$

This holding for all $|\xi| \ge 1$, and $|\widehat{\mu_{\delta,U(1,x)}}(\xi)|$ being bounded by 1, we conclude, since $\theta > 1/2$, that $\int_{\mathbb{R}} |\widehat{\mu_{\delta,U(1,x)}}(\xi)|^2 d\xi < \infty$. Lemma 1.1 ensures us that the law of $\mu_{\delta,U(1,x)}$ has a density, for each $\delta > 0$. We conclude using Lemma 1.2 that $\mu_{U(1,x)}$ has a density on $\{\sigma^2 > 0\}$. □

5 Lévy-driven S.D.E.s

We conclude this paper with Lévy driven S.D.E.s. For simplicity, we restrict our study to the case of deterministic coefficients depending only on the position of the process. The result below extends without difficulty, as in the Brownian case, to S.D.E.s with random coefficients depending on the whole paths, under some adequate conditions.

We thus consider a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge0}, P)$ and a square-integrable compensated $(\mathcal{F}_t)_{t\ge0}$-Lévy process $(Z_t)_{t\ge0}$ without drift and without Brownian part. We denote by ν its Lévy measure. Its characteristic function is thus given by

$$\mathbb{E}\left[\exp(i\xi Z_t)\right] = \exp\left(-t\int_{\mathbb{R}_*}(1-e^{i\xi z}-i\xi z)\nu(dz)\right).$$

For $\sigma, b : \mathbb{R} \mapsto \mathbb{R}$, we consider the one-dimensional S.D.E.

$$X_t = x + \int_0^t \sigma(X_{s-})dZ_s + \int_0^t b(X_s)ds. \tag{5.1}$$

Our aim in this section is to prove the following result.

Theorem 5.1 *Assume that* $\int_{\mathbb{R}_*} z^2\nu(dz) < \infty$ *and that for some* $\lambda \in (3/4, 2)$, $c > 0$, $\xi_0 \geq 0$,

$$\forall\, |\xi| \geq \xi_0, \int_{\mathbb{R}_*} (1 - \cos(\xi z))\nu(dz) \geq c|\xi|^\lambda, \tag{5.2}$$

and for some $\gamma \in [1, 2]$ *(with necessarily* $\gamma \geq \lambda$*),*

$$\int_{\mathbb{R}_*} |z|^\gamma \nu(dz) < \infty. \tag{5.3}$$

We also assume that b *is measurable with at most linear growth, and that* σ *is Hölder continuous with exponent* $\theta \in (3\gamma/(2\lambda) - 1, 1]$. *If* $\lambda \in (3/4, 3/2)$, *we additionnaly suppose that* b *is Hölder continuous with index* $\alpha \in (3\gamma/(2\lambda) - \gamma, 1]$.
Let $(X_t)_{t\geq 0}$ *be a càdlàg* $(\mathcal{F}_t)_{t\geq 0}$*-adapted solution to (5.1). Then for all* $t > 0$, *the law of* X_t *has a density on the set* $\{x \in \mathbb{R},\ \sigma(x) \neq 0\}$.

Here again the (weak or strong) existence of solutions to (5.1) probably does not hold under the sole assumptions of Theorem 5.1. See Jacod [15] for many existence results.
Let us comment on this result. If (5.2) holds with $\lambda > 3/2$, we assume no regularity on the drift coefficient b. Observe here that no trick using a Girsanov Theorem may allow us to remove the drift, because there is a clear difference of nature between the paths of a pure jump Lévy process with drift and without drift.

Assume that ν statisfies $\int_{\mathbb{R}_*} z^2\nu(dz) < \infty$ and the following property for some $\lambda \in (3/4, 2)$: there are $0 < c_0 < c_1$ such that for all $\epsilon \in (0, 1]$,

$$c_0\epsilon^{2-\lambda} \leq \int_{|z|\leq\epsilon} z^2\nu(dz) \leq c_1\epsilon^{2-\lambda}. \tag{5.4}$$

Then (5.2) holds and (5.3) holds with any $\gamma \in (\lambda, 2]$. For example, $\nu(dz) = z^{-1-\lambda}\mathbf{1}_{[0,1]}(z)dz$ satisfies (5.4), as well as $\nu(dz) = \sum_{n\geq 1} n^{\lambda-1}\delta_{1/n}$, or more generally $\nu(dz) = \sum_{n\geq 1} n^{\lambda\alpha-1}\delta_{n^{-\alpha}}$ with $\alpha > 0$.
Assume that (5.4) holds for some $\lambda \in (3/4, 2)$. Then our result holds in the following situations:
(i) $\lambda > 3/2$, σ is Hölder continuous with exponent $\theta > 1/2$;
(ii) $\lambda \in [1, 3/2]$, σ is Hölder continuous with index $\theta > 1/2$, b is Hölder continuous with exponent $\alpha > 3/2 - \lambda$;
(iii) $\lambda \in (3/4, 1]$, σ and b are Hölder continuous with exponent $\theta > 3/(2\lambda) - 1$.

Proof By scaling, it suffices to consider the case $t = 1$. We will often write the Lévy process as

$$Z_t = \int_0^t \int_{\mathbb{R}_*} z\tilde{N}(ds, dz),$$

where $\tilde{N}(ds, dz)$ is a compensated Poisson measure on $\mathbb{R}_+ \times \mathbb{R}_*$ with intensity measure $ds\nu(dz)$. Thus (5.1) rewrites as

$$X_t = x + \int_0^t \int_{\mathbb{R}_*} \sigma(X_{s-})z\tilde{N}(ds, dz) + \int_0^t b(X_s)ds. \tag{5.5}$$

Step 1. For $\epsilon \in (0, 1)$, we consider the random variable

$$Z_\epsilon := X_{1-\epsilon} + \int_{1-\epsilon}^1 \sigma(X_{1-\epsilon})dZ_s + \int_{1-\epsilon}^1 b(X_{1-\epsilon})ds.$$

For $\delta > 0$, consider the function f_δ of Lemma 1.2. Recall that f_δ is bounded and vanishes on $[0, \delta]$.

Conditioning with respect to $\mathcal{F}_{1-\epsilon}$ and using (5.2), we get for all $|\xi| \geq \xi_0/\delta$,

$$\begin{aligned}
&|\mathbb{E}\Big[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|)|\mathcal{F}_{1-\epsilon}\Big]| \\
&= f_\delta(|\sigma(X_{1-\epsilon})|)\left|\exp\left(i\xi X_{1-\epsilon} + i\xi\epsilon b(X_{1-\epsilon}) - \epsilon\int_{\mathbb{R}_*}(1 - e^{i\xi\sigma(X_{1-\epsilon})z} - i\xi\sigma(X_{1-\epsilon})z)\nu(dz)\right)\right| \\
&= f_\delta(|\sigma(X_{1-\epsilon})|)\exp\left(-\epsilon\int_{\mathbb{R}_*}(1-\cos(\xi\sigma(X_{1-\epsilon})z)\nu(dz)\right) \\
&\leq f_\delta(|\sigma(X_{1-\epsilon})|)\exp(-c\epsilon\delta^\lambda|\xi|^\lambda) \leq \exp(-c\epsilon\delta^\lambda|\xi|^\lambda).
\end{aligned}$$

We used that f_δ is bounded by 1 and vanishes on $[0,\delta]$ to obtain the two last inequalities.

Step 2. Recall that σ and b are Hölder continuous with exponent $\theta \in (0,1]$ and $\alpha \in [0,1]$ (when there is no regularity assumption on b, we say that it is Hölder with exponent 0). The goal of this Step is to show that for all $\epsilon \in (0,1)$,

$$I_\epsilon := \mathbb{E}[|X_1 - Z_\epsilon|^\gamma] \leq C\epsilon^{1+\theta} + C\epsilon^{\gamma+\alpha} \leq C\epsilon^{1+\zeta}, \tag{5.6}$$

where $\zeta := \min(\theta, \gamma+\alpha-1) \in (3\gamma/2\lambda - 1, 1]$ by assumption. We first show that for all $0 \leq s \leq t \leq 1$,

$$\mathbb{E}\left[\sup_{[0,1]}|X_s|^\gamma\right] \leq C, \quad \mathbb{E}[|X_t - X_s|^\gamma] \leq C|t-s|. \tag{5.7}$$

First, using (5.5), the Burkholder-Davies-Gundy inequality (see Dellacherie-Meyer [9]), the subadditivity of $x \mapsto x^{\gamma/2}$, the Hölder inequality, (5.3) and that b, σ have at most linear growth, we obtain, for all $t \in [0,1]$,

$$\begin{aligned}
\mathbb{E}\left[\sup_{u\in[0,t]}|X_u|^\gamma\right] \leq& C|x|^\gamma + C\mathbb{E}\left[\sup_{u\in[0,t]}\left|\int_0^u\int_{\mathbb{R}_*}\sigma(X_{s-})z\tilde{N}(ds,dz)\right|^\gamma\right] + C\mathbb{E}\left[\left(\int_0^t|b(X_s)|ds\right)^\gamma\right] \\
\leq& C|x|^\gamma + C\mathbb{E}\left[\left(\int_0^t\int_{\mathbb{R}_*}|\sigma(X_{s-})z|^2N(ds,dz)\right)^{\gamma/2}\right] + C\mathbb{E}\left[\left(\int_0^t|b(X_s)|ds\right)^\gamma\right] \\
\leq& C|x|^\gamma + C\mathbb{E}\left[\int_0^t\int_{\mathbb{R}_*}|\sigma(X_{s-})z|^\gamma N(ds,dz)\right] + Ct^{\gamma-1}\mathbb{E}\left[\int_0^t|b(X_s)|^\gamma ds\right] \\
\leq& C|x|^\gamma + C\int_0^t\int_{\mathbb{R}_*}\mathbb{E}[|\sigma(X_{s-})|^\gamma]|z|^\gamma\nu(dz)ds + Ct^{\gamma-1}\int_0^t\mathbb{E}[|b(X_s)|^\gamma]ds \\
\leq& C|x|^\gamma + C\int_0^t\mathbb{E}[1+|X_s|^\gamma]ds,
\end{aligned}$$

and the Gronwall Lemma allows us to conclude that $\mathbb{E}[\sup_{[0,1]}|X_s|^\gamma] \leq C$. The same arguments ensure us that for $0 \leq s \leq t \leq 1$, $\mathbb{E}[|X_t - X_s|^\gamma] \leq C\int_s^t\mathbb{E}[1+|X_u|^\gamma]du$, whence the second inequality of (5.7). We may now check (5.6). Using similar arguments and the Hölder continuity assumptions, we obtain

$$\begin{aligned}
I_\epsilon \leq& C\mathbb{E}\left[\left(\int_{1-\epsilon}^1\int_{\mathbb{R}_*}|(\sigma(X_{s-}) - \sigma(X_{1-\epsilon}))z|^2N(ds,dz)\right)^{\gamma/2}\right] + C\mathbb{E}\left[\left(\int_{1-\epsilon}^1|b(X_s) - b(X_{1-\epsilon})|ds\right)^\gamma\right] \\
\leq& C\int_{1-\epsilon}^1\mathbb{E}\left[|\sigma(X_{s-}) - \sigma(X_{1-\epsilon})|^\gamma\right]ds + C\epsilon^{\gamma-1}\int_{1-\epsilon}^1\mathbb{E}\left[|b(X_{s-}) - b(X_{1-\epsilon})|^\gamma\right]ds \\
\leq& C\int_{1-\epsilon}^1\mathbb{E}\left[|X_s - X_{1-\epsilon}|^{\gamma\theta}\right]ds + C\epsilon^{\gamma-1}\int_{1-\epsilon}^1\mathbb{E}\left[|X_s - X_{1-\epsilon}|^{\alpha\gamma}\right]ds \\
\leq& C\int_{1-\epsilon}^1\mathbb{E}\left[|X_s - X_{1-\epsilon}|^\gamma\right]^\theta ds + C\epsilon^{\gamma-1}\int_{1-\epsilon}^1\mathbb{E}\left[|X_s - X_{1-\epsilon}|^\gamma\right]^\alpha ds \leq C\epsilon^{1+\theta} + C\epsilon^{\gamma+\alpha},
\end{aligned}$$

where we finally used (5.7).

Step 3. Let $\delta > 0$ be fixed, and consider the measure $\mu_{\delta,X_1}(dx) = f_\delta(|\sigma(x)|)\mu_{X_1}(dx)$, where μ_{X_1} is the law of X_1. Then as usual, for all $\xi \in \mathbb{R}$, all $\epsilon \in (0,1)$, we may write

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le |\mathbb{E}[e^{i\xi Z_\epsilon} f_\delta(|\sigma(X_{1-\epsilon})|)]| + |\xi|\mathbb{E}[|X_1 - Z_\epsilon|] + \mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|].$$

Using the Hölder continuity of σ and (5.7), one easily gets (recall that $0 < \theta \le 1 \le \gamma$ by assumption) $\mathbb{E}[|f_\delta(|\sigma(X_1)|) - f_\delta(|\sigma(X_{1-\epsilon})|)|] \le C\mathbb{E}[|X_1 - X_{1-\epsilon}|^\theta] \le C\epsilon^{\theta/\gamma}$. Next, using Steps 1 and 2, we obtain, for all $\epsilon \in (0,1)$, all $|\xi| \ge \xi_0/\delta$,

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le \exp(-c\delta^\lambda \epsilon|\xi|^\lambda) + C|\xi|\epsilon^{(1+\zeta)/\gamma} + C\epsilon^{\theta/\gamma}.$$

For each $|\xi| \ge \xi_1 \vee (\xi_0/\delta)$ we choose $\epsilon := (\log|\xi|)^2/|\xi|^\lambda \in (0,1)$ (this holds if ξ_1 is large enough). This gives

$$|\widehat{\mu_{\delta,X_1}}(\xi)| \le \exp(-c\delta^\lambda(\log|\xi|)^2) + C(\log|\xi|)^{2(1+\zeta)/\gamma}/|\xi|^{\lambda(1+\zeta)/\gamma - 1} + C(\log|\xi|)^{2\theta/\gamma}/|\xi|^{\lambda\theta/\gamma}.$$

This holding for all $|\xi| \ge \xi_1 \vee (\xi_0/\delta)$, and $\widehat{\mu_{\delta,X_1}}$ being bounded by 1, we get that $\int_{\mathbb{R}} |\widehat{\mu_{\delta,X_1}}(\xi)|^2 d\xi < \infty$. Indeed, $\lambda(1+\zeta)/\gamma - 1 > 1/2$ (because $\zeta > 3\gamma/2\lambda - 1$) and $\lambda\theta/\gamma > 1/2$ (because $\theta > 3\gamma/2\lambda - 1$ and $\lambda \le \gamma$). Lemma 1.1 implies that the measure μ_{δ,X_1} has a density (for $\delta > 0$ fixed), and we conclude using Lemma 1.2 that μ_{X_1} has a density on $\{|\sigma| > 0\}$. □
